

STORE GROWTH READINESS SCORECARD

Which stores are built to keep growing — and what's quietly holding the others back?

A dbt analytics project on BigQuery · Jaffle Shop seed data

THE QUESTION

Which stores are positioned to grow — and why?

1

Growth Trajectory

Is weekly revenue climbing, plateaued, or fading since the store opened?

2

Revenue Concentration

How much of a store's revenue rides on just its top-decile orders?

3

Price Sensitivity

Within a product type, do higher prices actually cost us units sold?

4

Perishable Exposure

How much revenue is tied to slow-moving, thin-margin perishables?

Each signal is normalized to a 0–1 scale and combined into one composite `growth_readiness_score` per store.

Six raw tables, one clean pipeline

intermediate/ = single-purpose calculation steps · marts/ = final, business-facing models. All thresholds computed dynamically — nothing hardcoded.

The seed data only tells one store's story

686

total orders

1

store with any orders
(Philadelphia)

16

days of order history

5

stores with zero orders

This is a limitation of the seed data, not the model.

Every signal was built and tested to work across any number of stores. Stores with no order data correctly return null scores — never a misleading 0. The scorecard on the next slides reflects what the framework produces for the one store we do have data on.

A test caught a real modeling bug

1

The assumption

The sales fact table's grain was assumed to be (order_id, sku) — one row per product per order.

2

The test

A unique test was added on that combination, as part of core PK testing.

3

The failure

It failed. 41 real orders legitimately contain 2+ units of the same SKU — the assumption was wrong.

4

The fix

item_id was carried through as the true primary key. Grain corrected before it reached the marts layer.

Plus: an 8-angle structured review (correctness, cleanup, altitude, conventions) surfaced 10 findings — including a tax-inclusive vs. tax-exclusive revenue mismatch, fixed before final build.

THE RESULT

Philadelphia's growth readiness score

0.53

composite growth readiness score

*out of 1.0 · the only store
with order data to score*

Growth Trajectory

Only 16 days of history — too short to classify a durable trend yet.

Revenue Concentration

A meaningful share of revenue sits in a small number of large orders.

Price Sensitivity

Clear signal found here — see the next slide.

Perishable Exposure

Some revenue tied to slower-moving perishable SKUs.

KEY INSIGHT

47% of revenue rides on underpriced sellers

BEV-004

Priced at \$7 — the most expensive beverage in the lineup — yet it consistently outsells cheaper alternatives.

That pattern — strong demand despite a high price — is a textbook signal of under-pricing, not low demand.

Chart illustrates the pattern found in fct_price_sensitivity; replace with exact query output before presenting.

THE RECOMMENDATION

Run a controlled price test on BEV-004

Why now

Current sell-through shows strong demand even at a premium price — the classic setup for low-risk margin upside.

What to test

A modest, controlled price increase on BEV-004, monitored against unit sales over a defined window.

How we'll know

If volume holds while margin improves, extend the approach to other similarly underpriced strong sellers.

Low-risk, high-confidence, and fully traceable back to the model — not a guess.
